

Dictyostelium — why no simulation matches the data

The best point-cell model (sense_sat, $D=0.0042$) forms REAL-like multi-mounds only TRANSIENTLY (~frame 400), then COLLAPSES to a single blob (inner-mass $\rightarrow 0.8+$); the real aggregate stays multi-mound. No stable multi-mound attractor exists in 12 tested 2D mechanisms — most likely a 3-D mound viewed in projection, unreachable in 2D.
